Simple Linear Regression

Introduction

Dr. Maria Tackett

Topics

 Use simple linear regression to describe the relationship between a quantitative predictor and quantitative response variable.

Topics

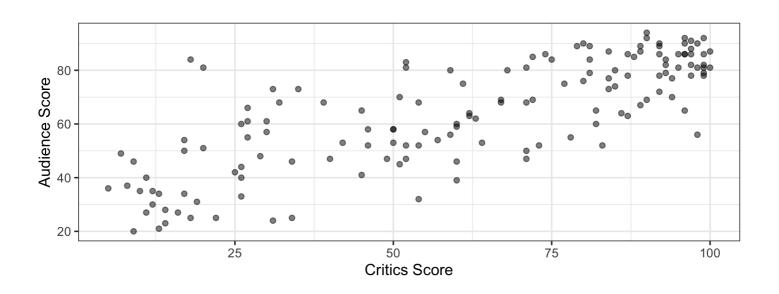

- Use simple linear regression to describe the relationship between a quantitative predictor and quantitative response variable.
- Estimate the slope and intercept of the regression line using the least squares method.

Topics

- Use simple linear regression to describe the relationship between a quantitative predictor and quantitative response variable.
- Estimate the slope and intercept of the regression line using the least squares method.
- Interpret the slope and intercept of the regression line.

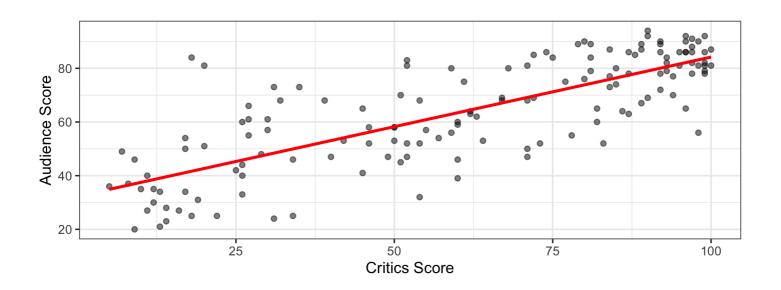

Movie ratings data

The data set contains the "Tomatometer" score (**critics**) and audience score (**audience**) for 146 movies rated on rottentomatoes.com.

Movie ratings data

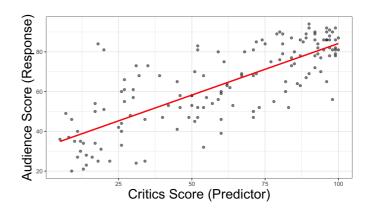

We want to fit a line to describe the relationship between the critics score and audience score.

Terminology

The **response**, *Y*, is the variable describing the outcome of interest.

The **predictor**, *X*, is the variable we use to help understand the variability in the response.

Regression model

A **regression model** is a function that describes the relationship between the response, Y, and the predictor, X.

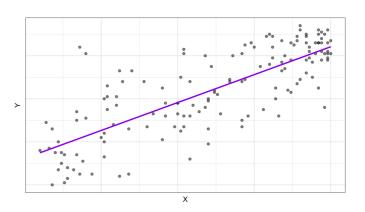

$$Y = Model + Error$$

= $f(X) + \epsilon$
= $\mu_{Y|X} + \epsilon$

Y = Model + Error

$$= \mathbf{f}(\mathbf{X}) + \epsilon$$

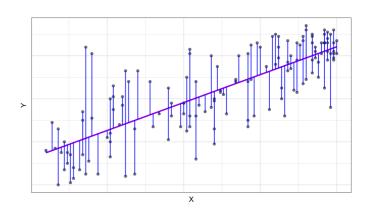

$$=\mu_{Y|X}+\epsilon$$

Y = Model + Error

$$= \mathbf{f}(\mathbf{X}) + \boldsymbol{\epsilon}$$

$$=\mu_{Y|X}+\epsilon$$

Simple linear regression

When we have a quantitative response, Y, and a single quantitative predictor, X, we can use a **simple linear regression** model to describe the relationship between Y and X.

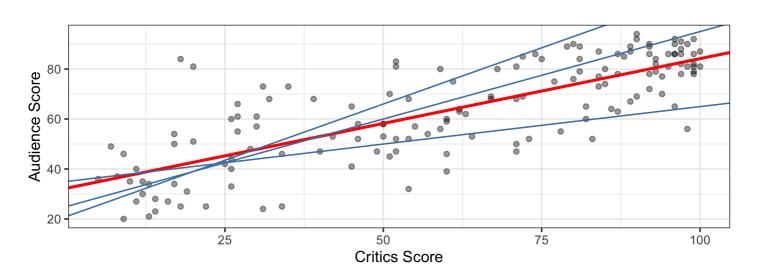

$$Y = \beta_0 + \beta_1 \mathbf{X} + \epsilon$$

 β_1 : Slope β_0 : Intercept

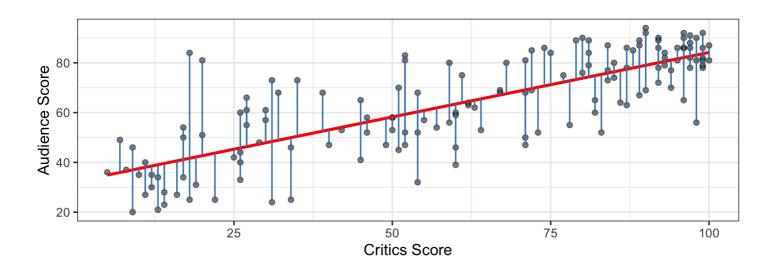

$$\hat{Y} = \hat{\beta}_0 + \hat{\beta}_1 X$$

$$\hat{Y} = \hat{\beta}_0 + \hat{\beta}_1 X$$

How do we choose values for $\hat{\beta}_1$ and $\hat{\beta}_0$?

Residuals

residual = observed - predicted = $y - \hat{y}$

• The residual for the i^{th} observation is

$$e_i$$
 = observed – predicted = $y_i - \hat{y}_i$

• The residual for the i^{th} observation is

$$e_i$$
 = observed – predicted = $y_i - \hat{y}_i$

The sum of squared residuals is

$$e_1^2 + e_2^2 + \dots + e_n^2$$

• The residual for the i^{th} observation is

$$e_i$$
 = observed – predicted = $y_i - \hat{y}_i$

The sum of squared residuals is

$$e_1^2 + e_2^2 + \dots + e_n^2$$

 The least squares line is the one that minimizes the sum of squared residuals

Estimating the slope

$$\hat{\beta}_1 = r \frac{s_Y}{s_X}$$

Estimating the slope

$$\hat{\beta}_1 = r \frac{s_Y}{s_X}$$

$$s_X = 30.169$$

$$s_Y = 20.024$$

$$r = 0.781$$

Estimating the slope

$$\hat{\beta}_1 = r \frac{S_Y}{S_X}$$

$$s_X = 30.169$$

$$s_Y = 20.024$$

$$r = 0.781$$

$$\hat{\beta}_1 = 0.781 \times \frac{20.024}{30.169}$$

$$= 0.518$$

Estimating the intercept

$$\hat{\beta}_0 = \bar{Y} - \hat{\beta}_1 \bar{X}$$

Estimating the intercept

$$\hat{\beta}_0 = \bar{Y} - \hat{\beta}_1 \bar{X}$$

$$\bar{x} = 60.850$$

$$\bar{y} = 63.877$$

$$\hat{\beta}_1 = 0.518$$

Estimating the intercept

$$\hat{\beta}_0 = \bar{Y} - \hat{\beta}_1 \bar{X}$$

$$\bar{x} = 60.850$$

$$\bar{y} = 63.877$$

$$\hat{\beta}_1 = 0.518$$

$$\hat{\beta}_0 = 63.877 - 0.518 \times 60.850$$

$$= 32.296$$

Interpreting slope & intercept

audience =
$$32.296 + 0.518 \times \text{critics}$$

Interpreting slope & intercept

audience =
$$32.296 + 0.518 \times \text{critics}$$

Slope: For every one point increase in the critics score, we expect the audience score to increase by 0.518 points, on average.

Interpreting slope & intercept

audience =
$$32.296 + 0.518 \times \text{critics}$$

Slope: For every one point increase in the critics score, we expect the audience score to increase by 0.518 points, on average.

Intercept: If the critics score is 0 points, we expect the audience score to be 32.296 points.

Does it make sense to interpret the intercept?

Does it make sense to interpret the intercept?

- ✓ Interpret the intercept if
 - the predictor can feasibly take values equal to or near zero.
 - there are values near zero in the data.

Does it make sense to interpret the intercept?

- ✓ Interpret the intercept if
 - the predictor can feasibly take values equal to or near zero.
 - there are values near zero in the data.

Otherwise, don't interpret the intercept!

 Used simple linear regression to describe the relationship between a quantitative predictor and quantitative response variable.

- Used simple linear regression to describe the relationship between a quantitative predictor and quantitative response variable.
- Used the least squares method to estimate the slope and intercept.

- Used simple linear regression to describe the relationship between a quantitative predictor and quantitative response variable.
- Used the least squares method to estimate the slope and intercept.
- We interpreted the slope and intercept.
 - **Slope**: For every one unit increase in x, we expect y to change by $\hat{\beta}_1$ units, on average.
 - Intercept: If x is 0, then we expect y to be $\hat{\beta}_0$ units.
